A Recap of Traditional Effect Types

Effects and Effect Types

Effects are the way programs interact with their environment

Including I/O, concurrency, exceptions, nondeterminism, probability

Effect types statically track use of effects in types

Traditional Effect Types

`inc : Int → Int`

`inc x = x + 1`

`app : (Int → Int) → Int → Int`

`app f x = f x`

 `app inc 42`

`43 : Int`

Traditional Effect Types

$\text{inc} : \text{Int} \rightarrow \{\} \text{Int}$
 $\text{inc } x = x + 1$

traditional effect types annotate each function arrow with the effects it uses

$\text{app} : (\text{Int} \rightarrow \{\} \text{Int}) \rightarrow \{\} \text{Int} \rightarrow \{\} \text{Int}$
 $\text{app } f \ x = f \ x$

Traditional Effect Types

`inc : Int → {} Int`

`inc x = x + do ask ()`

`ask : 1 ⇒ Int` takes a unit and returns an integer

`app : (Int → {} Int) → {} Int → {} Int`

`app f x = f x`

Traditional Effect Types

`inc : Int  $\rightarrow$  {ask} Int`

`inc x = x + do ask ()`

`app : (Int  $\rightarrow$  {} Int)  $\rightarrow$  {} Int  $\rightarrow$  {} Int`

`app f x = f x`

Traditional Effect Types

`inc : Int  $\rightarrow$  {ask} Int`

`inc x = x + do ask ()`

`app : (Int  $\rightarrow$  {ask} Int)  $\rightarrow$  {ask} Int  $\rightarrow$  {ask} Int`

`app f x = f x`

we also need to annotate function arrows of app
to allow effectful arguments

Traditional Effect Types

`inc : Int  $\rightarrow$  {ask} Int`

`inc x = x + do ask ()`

`app :  $\forall e .$  (Int  $\rightarrow$  {e} Int)  $\rightarrow$  {e} Int  $\rightarrow$  {e} Int`

`app f x = f x`

the most general type requires **effect polymorphism**

Traditional Effect Types

$\text{inc} : \forall e . \text{Int} \rightarrow \{\text{ask}, e\} \text{Int}$

$\text{inc } x = x + \mathbf{do} \text{ ask } ()$

$\text{app} : \forall e . (\text{Int} \rightarrow \{e\} \text{Int}) \rightarrow \{e\} \text{Int} \rightarrow \{e\} \text{Int}$

$\text{app } f \ x = f \ x$

$\text{ans} : \forall e . (1 \rightarrow \{\text{ask}, e\} \text{Int}) \rightarrow \{e\} \text{Int}$

$\text{ans } f = \mathbf{handle} \ f \ () \ \mathbf{with} \ \{ \text{ask } () \ r \mapsto r \ 37 \}$

handler's argument is allowed to use ask
plus any other effects abstracted by e

a handler of ask which resumes the continuation r with 37

Traditional Effect Types

$\text{inc} : \forall e . \text{Int} \rightarrow \{\text{ask}, e\} \text{Int}$

$\text{app} : \forall e . (\text{Int} \rightarrow \{e\} \text{Int}) \rightarrow \{e\} \text{Int} \rightarrow \{e\} \text{Int}$

$\text{ans} : \forall e . (1 \rightarrow \{\text{ask}, e\} \text{Int}) \rightarrow \{e\} \text{Int}$

Effect variables are verbose

Adding traditional effect types to existing languages requires significant rewriting of type signatures such as `app`

Can we get rid of these effect variables?

Our Proposal: Modal Effect Types

Modal Effect Types

👁️ Let us take a closer look at app

$\text{app} : \forall e. (\text{Int} \rightarrow \{e\} \text{Int}) \rightarrow \{e\} \text{Int} \rightarrow \{e\} \text{Int}$

$\text{app } f \ x = f \ x$

😡 This is unfair. *The app itself does not even mention any effects!*

🤔 Why don't we just track this fact?

💧 But effect types are **entangled** with function arrows in a traditional effect system

💡 Let's **decouple** effect types from function arrows

Ambient Effect Context

Typing judgements track **effect contexts**, i.e., effects provided by the context

$$\text{app} : \underbrace{(\text{Int} \rightarrow \text{Int})}_{@ E} \rightarrow \underbrace{\text{Int} \rightarrow \text{Int}}_{@ E}$$

ambient effect context (part of the typing judgement)

Both the argument and result of app share the same effect context E

Absolute Modality

An **absolute modality** $[F]$ specifies an effect context F in a type

$\text{app} : (\text{Int} \rightarrow \text{Int}) \rightarrow \text{Int} \rightarrow \text{Int}$

Absolute Modality

An **absolute modality** $[F]$ specifies an effect context F in a type

$\text{app} : \overbrace{[]}^{\text{@ } E} \underbrace{((\text{Int} \rightarrow \text{Int}) \rightarrow \text{Int} \rightarrow \text{Int})}_{\text{@ } .}$

$[]$ overwrites E to empty

app itself is a pure function

The empty **absolute modality** $[]$ indicates that app uses no effects

By *subeffecting* we can still apply app in any effect context E

Absolute Modality

Similarly for `inc`

`inc` : $\forall e . \text{Int} \rightarrow \{\text{ask}, e\} \text{Int}$

`inc x = x + do ask ()`

Absolute Modality

Similarly for `inc`

`inc : [ask](Int → Int)`
`inc x = x + do ask ()`

The **absolute modality** `[ask]` indicates that `inc` uses `ask`

By *subeffecting* we can still apply `inc` in any effect context `E` containing `ask`

Relative Modality

A **relative modality** $\langle F \rangle$ specifies an extension F to the effect context

ans : $\forall e . (1 \rightarrow \{\text{ask}, e\} \text{ Int}) \rightarrow \{e\} \text{ Int}$

Relative Modality

A **relative modality** $\langle F \rangle$ specifies an extension F to the effect context

The **relative modality** $\langle \text{ask} \rangle$ indicates that ans ' argument may *additionally* use ask meanwhile can still use effects E from the context

In other words, ans **handles** ask

Relative Modality

A **relative modality** $\langle F \rangle$ specifies an extension F to the effect context

$\underbrace{\quad \quad \quad}_{@ \cdot} \quad \underbrace{\quad \quad \quad}_{@ \text{ ask}}$

ans : $[](\langle \text{ask} \rangle(1 \rightarrow \text{Int}) \rightarrow \text{Int})$

The **absolute modality** $[]$ indicates that ans itself does not use effects

By sub-effecting we may still use ans with other effects

Modal Effect Types

inc : [ask](Int $\rightarrow$ Int)

app : []((Int $\rightarrow$ Int) $\rightarrow$ Int $\rightarrow$ Int)

ans : [](<ask>(1 $\rightarrow$ Int) $\rightarrow$ Int)

Modal Effect Types

`inc : [ask](Int → Int)`

`app : (Int → Int) → Int → Int`

`ans : <ask>(1 → Int) → Int`

Convention: global function definitions implicitly have a `[]`

Modal Effect Types

`inc : [ask](Int → Int)`

`app : (Int → Int) → Int → Int`

`ans : <ask>(1 → Int) → Int`

Compose them together

▶ `ans (fun () → app inc 42)`

`79 : Int`

A Case Study: Cooperative Concurrency

Cooperative Concurrency 🧵

With traditional effect types:

effect Coop = fork : 1 $\Rightarrow$ Bool | suspend : 1 $\Rightarrow$ 1

data Proc e = proc (List (Proc e) $\rightarrow$ {e} 1)

-- push a process into a queue

push : $\forall$ e . Proc $\rightarrow$ {e} List Proc $\rightarrow$ {e} List Proc

-- run the first process in the queue

next : $\forall$ e . List Proc $\rightarrow$ {e} 1

schedule : $\forall$ e . (1 $\rightarrow$ {Coop, e} 1) $\rightarrow$ {e} List Proc $\rightarrow$ {e} 1

schedule m = **handle** m () **with**

return () $\Rightarrow$ **fun** q $\rightarrow$ next q,

suspend () r $\Rightarrow$ **fun** q $\rightarrow$ next (push (proc (r ())) q),

fork () r $\Rightarrow$ **fun** q $\rightarrow$ r true (push (proc (r false)) q)

Cooperative Concurrency 🧵

With modal effect types:

effect Coop = fork : 1 $\Rightarrow$ Bool | suspend : 1 $\Rightarrow$ 1

data Proc = proc (List Proc $\rightarrow$ 1)

-- push a process into a queue

push : [] (Proc $\rightarrow$ List Proc $\rightarrow$ List Proc)

-- run the first process in the queue

next : [] (List Proc $\rightarrow$ 1)

schedule : [] (<Coop>(1 $\rightarrow$ 1) $\rightarrow$ List Proc $\rightarrow$ 1)

schedule m = **handle** m () **with**

return () $\Rightarrow$ **fun** q $\rightarrow$ next q,

suspend () r $\Rightarrow$ **fun** q $\rightarrow$ next (push (proc (r ())) q),

fork () r $\Rightarrow$ **fun** q $\rightarrow$ r true (push (proc (r false)) q)

A Quick Look at the Core Calculus 🙄🙄

A Tale of Locks and Keys

mod introduces a modality and a lock

$$\frac{\Gamma, \text{lock_}[ask] \vdash \text{fun } x \rightarrow f \ x : \text{Int} \rightarrow \text{Int} \ @ \ ask}{\Gamma \vdash \text{mod_}[ask] (\text{fun } x \rightarrow f \ x) : [ask](\text{Int} \rightarrow \text{Int}) \ @ \ E}$$

the ambient effect context is overwritten to ask

locks control usage of variables

modality transformation: the key  to the lock

$$\frac{[] \Rightarrow [ask]}{f : _[] \text{Int} \rightarrow \text{Int}, \text{lock_}[ask] \vdash f : \text{Int} \rightarrow \text{Int} \ @ \ ask}$$
$$\frac{\Gamma \vdash V : [](\text{Int} \rightarrow \text{Int}) \ @ \ E \quad \Gamma, f : _[] \text{Int} \rightarrow \text{Int} \vdash M : A \ @ \ E}{\Gamma \vdash \text{let mod_}[] f = V \text{ in } M : A \ @ \ E}$$

let mod eliminates a modality and introduces a binder with a modality

More in the Paper

More in the Paper

- MET: a core calculus with modal effect types
 - Based on **multimodal type theory** (Gratzer et al. 2020)
 - Inspired by languages **Frank** (Lindley et al. 2017) and **Effekt** (Brachthäuser et al. 2020)
- Masking $\langle E \triangleright$ (the full syntax of relative modality is $\langle E \mid F \rangle$)
- Type soundness and effect safety
- Extensions to MET: parametric polymorphism, ADT
- Simple bidirectional typing for MET
- Encoding a *fragment* of traditional effect types into MET without the requirement of effect variables

Ongoing and Future Work

- Rows and Capabilities as *Modal Effects*.
 - a uniform framework for encoding different effect systems
 - conditionally accepted by POPL
- Better type inference for modal types
- Formal comparison with capture tracking of Scala
- Denotational semantics and logical relations
- Higher-order effects

Takeaway

Do not track effects on every function arrow -- track them when needed!

$\text{inc} : \forall e . \text{Int} \rightarrow \{\text{ask}, e\} \text{Int}$

$\text{app} : \forall e . (\text{Int} \rightarrow \{e\} \text{Int}) \rightarrow \{e\} \text{Int} \rightarrow \{e\} \text{Int}$

$\text{ans} : \forall e . (1 \rightarrow \{\text{ask}, e\} \text{Int}) \rightarrow \{e\} \text{Int}$

data $\text{Proc } e = \text{proc } (\text{List } (\text{Proc } e) \rightarrow \{e\} 1)$

$\text{push} : \forall e . \text{Proc} \rightarrow \{e\} \text{List Proc} \rightarrow \{e\} \text{List Proc}$

$\text{next} : \forall e . \text{List Proc} \rightarrow \{e\} 1$

$\text{schedule} : \forall e . (1 \rightarrow \{\text{Coop}, e\} 1) \rightarrow \{e\} \text{List Proc} \rightarrow \{e\} 1$

Takeaway

Do not track effects on every function arrow -- track them when needed!

inc : [ask](Int $\rightarrow$ Int)

app : []((Int $\rightarrow$ Int) $\rightarrow$ Int $\rightarrow$ Int)

ans : [](<ask>(1 $\rightarrow$ Int) $\rightarrow$ Int)

data Proc = proc (List Proc $\rightarrow$ 1)

push : [](Proc $\rightarrow$ List Proc $\rightarrow$ List Proc)

next : [](List Proc $\rightarrow$ 1)

schedule : [](<Coop>(1 $\rightarrow$ 1) $\rightarrow$ List Proc $\rightarrow$ 1)

(P.S. I'm looking for a postdoc position)
